Abdominal Paracentesis Standard Operating Procedure UHL Gastroenterology (LocSSIPs)

Change Description	Reason for Change
□ [·] Change in format	I Trust requirement

APPROVERS	POSITION	NAME	
Person Responsible for Procedure:	Consultant Hepatologist	Dr Toby Delahooke	
SOP Owner:	Consultant Hepatologist	Dr Toby Delahooke	
Sub-group Lead:	Consultant Hepatologist	Dr Ka-Kit Li	

Appendices in this document:

Appendix 1: UHL Safer Surgery Abdominal Paracentesis Checklist Appendix 2 : Patient Information Leaflet for *Having an abdominal tap/drain to remove fluid from around your tummy* Available at: <u>Having an abdominal tap/ drain to remove fluid from around your tummy</u> (leicestershospitals.nhs.uk)

Introduction and Background:

This SOP is based on the <u>clinical guidelines</u> produced by the BSG, EASL, AASLD. Reference has been made to the "<u>Paracentesis for Malignant Ascites Procedure SOP</u>" of Doncaster and Bassetlaw Hospitals NHS trust and Oxford Medical Education Website entry on "<u>Ascitic drain insertion</u>".

The SOP has been based on the National Safety Standards for Invasive Procedures template for Local Safety Standards for Invasive Procedures (LocSSIPs). Quick link to Safer Surgery Checklist: <u>Paracentesis checklist</u>

Abdominal paracentesis is a therapeutic procedure that is used to drain ascites from the abdomen.

Ascites: An accumulation of fluid within the peritoneal cavity of the abdomen.

Paracentesis: The procedure of removing ascitic fluid from the abdominal cavity. The commonest context in which this occurs is following the accumulation of hepatic ascites due to cirrhosis of the liver. However, it is sometimes also required to drain malignant ascites that can occur most commonly in gastric, ovarian, pancreatic, breast and bronchial malignancy. It can occur less commonly in congestive cardiac failure and protein depletion.

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 2 of 21 Version: 2

Paracentesis is a simple procedure which can be performed as a day case or as an inpatient. In tense ascites there may be up to 18 litres of ascites present. Removal of 4–6 litres is usually enough to give symptomatic relief. Removal of more than 6 litres rarely causes hypovolemia and adverse effects, but may give symptom relief for longer until the ascites reaccumulates.

Symptoms: Ascites can be distressing and be associated with abdominal distension, abdominal pain, nausea, vomiting, early satiety, anorexia, lower body oedema and breathlessness.

Benefits: Paracentesis aims to improve the symptoms of ascites. It can improve symptoms in up to 90% of cases, with some benefits seen after just two hours of drainage, although it may take breathlessness 72 hours to improve. It is less likely to improve the associated symptoms of oedema, fatigue, poor mobility and malaise. **Prognosis:** The development of hepatic ascites is associated with a mortality of 50% within two years of diagnosis. Once ascites becomes refractory to medical therapy, 50% die within six months. Therapeutic paracentesis or Transjugular Intrahepatic Portosystemic Shunt (TIPS) despite improving fluid management and patient quality of life do not improve long term survival without transplantation for most patients. Therefore, when any patient with cirrhosis develops ascites, suitability for liver transplantation should be considered. Attention should be given to renal function in patients with ascites as pre-transplant renal dysfunction leads to greater morbidity and delayed recovery following liver transplantation and is associated with a prolonged stay in the intensive care unit and hospital.

For malignant ascites, with the exception of chemotherapy sensitive carcinoma of the ovary, the prognosis is usually poor (2-3 months).

Paracentesis may not be appropriate if the prognosis is very short and the patient is rapidly deteriorating. If the prognosis is very short but patient has troublesome symptoms, a brief paracentesis of 1-2 litres can be considered to reduce discomfort.

Type of ascites: Ascites is usually either a transudate (protein level less than 30 g/l in ascitic fluid) or an exudate (protein level greater than 30 g/l).

- Transudates are usually seen in those with liver failure, from cirrhosis (resulting from portal hypertension). A trial of diuretics may be appropriate if the renal function permits.
- Exudates are seen usually with intra-abdominal malignancy, and diuretics are unlikely to be helpful. If there is uncertainty regarding the type of ascites and whether diuretics may help, a serum ascites albumin gradient (SAAG) can be calculated. This is done by sending a specimen of ascitic fluid to the biochemistry laboratory for measurement of protein and albumin levels. The ascitic albumin level is subtracted from the serum level and if the value is greater than 11 g/l, a trial of diuretics may be helpful post drainage to slow the rate of reaccumulation.

Indications for procedure:

- Pain, discomfort or tightness due to stretching of the abdominal wall.
- Dyspnoea, usually exacerbated by exertion, due to upward pressure on the diaphragm.
- Nausea, vomiting and dyspepsia due to 'squashed stomach syndrome'.
- Patients are usually symptomatic only when the abdominal wall is tensely distended.

Contraindications to paracentesis:

- Local infection
 - o Choose another site
- Pregnancy
- Obstruction/ileus

Cautions – but not contraindications

- Coagulopathy (INR greater than 2.0)
 - Attempt to correct INR to less than 1.5 if possible.

Trust Reference Number: C31/2019 Revision date: October 2023 University Hospitals of Leicester NHS NHS Trust Review date: October 2026	STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2	2010
NHS Trust Review date: October 2026			
Leicester Royal Infirmary (LRI) Page 3 of 21 Version: 2	University Hospitals of Leicester	Review date: Octo	ber 2026
	Leicester Royal Infirmary (LRI)	Page 3 of 21	Version: 2

• Platelets less than 50

Thrombocytopenia and coagulopathy is often present in liver disease and though it is a caution, it not a contraindication to paracentesis or drainage. The incidence of clinically significant bleeding is low; routine FFP or platelets is not indicated

- Organomegaly
- Distended bladder
- Abdominal adhesions

Complications of paracentesis:

- Total paracentesis is associated with significant haemodynamic effects. It has been assumed wrongly
 that total paracentesis of large volumes of ascites (>10 litre) leads to circulatory collapse. Large volume
 paracentesis (average >10 litre over 2–4 hours) causes a marked reduction in intra- abdominal and
 inferior vena cava pressure, leading to a decrease in right atrial pressure and an increase in cardiac
 output. These haemodynamic changes are maximal at three hours. Pulmonary capillary wedge pressure
 decreases at six hours and continues to fall further in the absence of colloid replacement. On average,
 blood pressure decreases by 8 mm Hg. The severity of post-paracentesis circulatory dysfunction
 correlates inversely with patient survival. There are anecdotal reports of some patients with advanced
 liver disease developing quite severe hypotension post-paracentesis, but this rarely occurs.
- The paracentesis site may continue to leak ascitic fluid post procedure. This may rarely continue to leak over days to weeks requiring a stoma bag to collect fluid. The patient needs to be warned about the possible leaking which may otherwise cause distress.
- Symptoms of dizziness, fatigue and malaise (up to 3%)
- Perforation of an abdominal viscus e.g. bowel perforation, is a risk especially if intestinal obstruction is present.
- Haemorrhage (a particular risk if the platelets are low) 1-2%. Blood stained ascites is common in malignant ascites and does not necessarily indicate a complication.
- Infection is a rare complication providing an aseptic technique is used.
- Pulmonary embolus from a dislodged thrombus (<1%)

Alternatives to paracentesis

• Diuretics

Diuretics can be considered but it takes 4-8 weeks to eliminate the excess fluid. The patients most likely to respond to diuretic therapy are those with liver failure, from cirrhosis. However, studies have shown increase renal dysfunction using this approach compared to large volume paracentesis for tense ascites.

- Measure baseline urea and electrolytes
- Measure weight prior to starting diuretics
- Start with spironolactone 100mg mane
- Increase dose by 100mg every 4 days to achieve a weight loss of 0.5-1kg/24hours
- Typical maintenance dose is 300mg mane
- Consider adding furosemide 40mg mane if desired weight loss not achieved after 2 weeks(max 80mg 9am and 12pm)
- Monitor U&Es carefully as electrolyte disturbance (particularly hyperkalaemia) and hypotension may occur.
- Stop diuretics if do not achieve satisfactory reduction in ascites, cause renalimpairment or not tolerated.

• Other treatment options

o TIPS: Has been recommended by NICE as a treatment for diuretic resistant or intolerant

Inpatients

For inpatients with hepatic ascites, referral should then be made to a doctor or PA who is trained and

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 5 of 21 Version: 2

competent in performing the procedure within the managing team (See <u>Workforce – Staffing requirements</u> section below). If there is no one competent to perform the procedure, then the Specialty Registrar for Gastroenterology oncall should be contacted to discuss the case (07985459112). For patients with malignant ascites then the Oncology ANP (currently Annie Law) should be contacted through switchboard. If the ANP is unavailable then the patient should be discussed with the oncall oncology registrar.

The decision as to whether the patient requires a radiologically placed drain will need to be made on all patients referred for an ultrasound preprocedure (see indications below) and based on a discussion between the referring doctor and the radiologist on its relative merits. Often marking of the most suitable site may occur which will allow the drain to be placed safely on the ward. However, if the insertion is Unsuccessful following this then a radiologically placed drain should be attempted if appropriate.

Day case patients

Ambulatory patients that are requiring recurrent paracentesis due to diuretic resistant or intolerant ascites can be referred a consultant Hepatologist secretary on 0116 258 6480. If advice is required to the suitability for paracentesis then directly contact the Hepatology specialty registrar or PA(phone ward 43 Leicester Royal Infirmary for contact details 0116 258 6239 or 6279). Currently these patients are being brought into either ward 43 or ward 42 Leicester Royal Infirmary to an available bed. In future, it is hoped that an ambulatory care bay on ward 43 is opened for this service. Only the Hepatology specialty registrar or PA are permitted to add patients to the list of patients needing daycase drainage. Patients that have any of the contraindications or cautions listed above should not have the procedure as a day case and should be admitted to one of the gastroenterology wards to have it performed. Patients that do not attend should be contacted within 24 hours to identify the reason for non-attendance and make alternative arrangements if necessary for drainage. Patients with recurrent malignant ascites should be referred to the Oncology ANP (currently Annie Law) via switchboard for arrangements to be made to attend the Osborne Day care area (0116 258 5263) for paracentesis.

LOROS

Patients that are approaching the end of their life and are being managed palliatively, can be referred to the palliative care team based at LOROS. If deemed appropriate the procedure may be performed there.

Patient preparation:

Investigations prior to procedure

• Ultrasound scan (USS)

If there is clinical evidence of substantial ascites in the form of tense abdomen and fluid thrill it is usually safe to proceed to drainage without USS imaging. An ultrasound scan will confirm the presence of ascites, and may determine if the fluid is 'pocketed' 'loculated' by tumour, adhesions etc.

A scan should be performed if:

- Malignant ascites.
- Ascitic fluid is not easily clinically identified i.e. possible other causes of abdominal distension such as hepatomegaly, abdominal tumour etc
- Difficulty with previous drainage or suspected loculation of ascites
- There is a chance of bowel obstruction

If there is any diagnostic uncertainty or the patient has previously been noted to have loculated ascites, arrange ultrasound scan with marking of maximum collection of ascites

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019	
Trust Reference Number: C31/2019	Revision date: October 2023	
University Hospitals of Leicester	Review date: October 2026	
Leicester Royal Infirmary (LRI)	Page 6 of 21 Version: 2	

If there is ascites clinically, or it is radiologically confirmed but the abdomen is not tense and there is no fluid thrill consider deferring the procedure as benefit will be limited.

If the radiologist marks the most appropriate site for the drain on the abdomen with an indelible pen then they should also make a dated, timed and signed entry into the medical notes describing the position so that at the time of the procedure it can be checked that this corresponds.

If an appropriately trained operator can performed bedside ultrasound then the paracentesis should be performed immediately afterwards.

• Blood tests

In order to proceed with a safe paracentesis, the following should be considered as a guide. In some cases if likely benefits outweigh the risks, paracentesis can be performed despite poor blood results. In these cases, the patient should be made aware of the increased risk as part of obtaining informed consent.

- A platelet count and clotting screen should be measured in at-risk patient.
- U&E should be taken if:
 - o More than 6 litres is to be removed, and the patient has oedema, or
 - o The patient is clinically dehydrated, or
 - o The patient has reacted badly to previous paracentesis

Caution should be exercised in those with:	Rationale
INR greater than 1.5	Risk of haemorrhage. Consider the use of
	vitamin K to normalise the INR before
	proceeding
Platelets below 50	Risk of haemorrhage
Significant anaemia	May be worsened by haemorrhage, lower reserves for
	coping with procedure. May make correct attribution of
	symptoms more difficult.
Low sodium (less than 126)	Poor prognostic indicator. Paracentesis can
	cause further electrolyte disturbance
Abnormal potassium	Paracentesis can cause further electrolyte
	disturbance
Poor renal function	Lower reserves for dealing with fluid shift
Hepatic impairment	Lower reserves for dealing with fluid shift, may
	be associated with raised INR
Low protein and albumin (less than 20)	Likely to re-accumulate more quickly due to low
	oncotic pressure (production rate
	exceeds drainage rate), leading to
	significant intravascular depletion
Low white cell count / neutropenia	Risk of infection
BEFORE THE PROCEDURE:	
Action	Rationale
Stop anticoagulation (3 days for warfarin, 2 days	Minimise the risk of haemorrhage
for Enoxaparin). See UHL guideline:	
Anticoagulant Bridging	
Therapy for Elective Surgery and	
Procedures B30/2016 if this is required.

Workforce – staffing requirements:

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 8 of 21 Version: 2

The minimum safe staffing is two; the person performing the procedure (the operator) and the assistant to open packs using an aseptic technique. This is no different in hours or out of hours.

Competency of the operator (doctor, ANP or PA) performing the procedure, will have been documented in their training portfolio following formative and a summative DOPs or equivilents. The operator should also have demonstrated knowledge of the UHL Consent to Treatment or Examination Policy A16/2002 Both the operator and the assistant should have up-to-date statutory and mandatory training on infection prevention. Operators that have been trained in pre-paracentesis ultrasound should have this competency recorded in the training portfolio.

If the operator requires assistance with the technical aspects of the procedure, then the assistant should call the registrar covering the ward. If the assistant needs help, then the sister in charge for the ward area should be called. For inpatients the patient's trained nurse will provide the post procedure monitoring.

Trained nursing support will also be required to monitor the patient after the procedure until discharge.

Ward checklist, and ward to procedure room handover:

No formal handover process is required for this procedure when performed as an inpatient. However, prior to performing the procedure the checklist (<u>See appendix C</u>) should be filled in by the operator and the assistant.

The procedure checklist (<u>see appendix C</u>) will be partially filled up by the nursing staff and will need to be finalised by the operator performing the procedure.

Procedural Verification of Site Marking:

The choice of the site of the procedure will depend on an initial examination of the patient. See the section below on <u>Performing the procedure</u>.

If the patient has had the site marked in radiology, then the medical notes should be checked for the entry by the radiologist that describes where this has been made and that it corresponds to mark on the patient and that 6 hours has not elapsed since this has been carried out.

If the operator has performed pre-paracentesis ultrasound to identify the site for drainage at the bedside, the paracentesis should take place immediately afterwards.

Team Safety Briefing:

The operator and the assistant must be present and it should take place in a private area on the ward. The safety briefing will involve checking that the both operator and the assistant have been trained to perform the procedure, that the patient is on the ward, the <u>equipment trolley</u> has been prepared and there are no immediate reasons why the procedure should not take place.

Monitoring:						

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 11 of 21 Version: 2

Immediately prior to the procedure and immediately after the procedure these observations should be made and recorded.

- Blood Pressure
- Pulse rate
- Respiratory rate
- Temp
- O2 Sats
- (Capillary Blood Glucose) CBGs

No monitoring is required during the procedure unless the patient becomes unwell or there is a complication with the procedure.

Prosthesis verification:

Not Applicable.

Prevention of retained Foreign Objects:

The main risk of retained foreign objects is if damage occurs to the flexible part of the paracentesis drain during its insertion or removal.

If any resistance is felt in the removal of the paracentesis drain, then a check should be made on the type of drain that has been inserted. If the drain has been inserted in radiology, then there is a string tie that has to be cut first.

Inspection of the complete drain should take place following its removal to ensure that it is fully intact. If there appears to be any part that is missing, then a surgical opinion should be sought.

Radiography:

See Patient preparation and List management and scheduling

Sign Out:

Upon the completion of the procedure the operator should confirm to the assistant that the procedure is complete (<u>See Appendix C Paracentesis checklist</u>)

Between them they should confirm:

- The trochar /needle has been removed from the drain.
- There is no bleeding around the drain site.
- The dressing is in place around the drain.
- All the connections are firmly tightened.
- Ascitic fluid is draining out of the drain into the tubing and into the bag without leakage.
- The patient is not in pain or showing any signs of peritonism.

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 12 of 21 Version: 2

- All sharps are disposed of safely.
- All non-sharp waste is disposed of in the appropriate bin
- The specimens for clinical chemistry, microbiology and histology are labelled correctly.
- An account of the procedure should then be documented in the notes. It should include the date and time it took place, the indication, that consent was given, that aseptic technique was used, the amount, type and strength of local anaesthetic used, the position of the drain, whether there were any complications, the samples that were taken and where they will be sent and any post procedure instructions for monitoring, IV fluids, analgesia, and how long to drain should remain in. This should then be signed and the operators name printed legibly.
- This post procedural care should be discussed with the assistant.

Handover:

If the assistant is not the nurse looking after the patient, then a handover to the nurse looking after the patient on the ward should take place (<u>See appendix C Paracentesis checklist</u>). This should cover:

- The procedure performed.
- The indication for the procedure.
- Whether there were any complications.
- Whether the patient received any medication or IV fluids during the procedure.
- The post procedure monitoring that is required.
- Instructions on IV fluid replacement required.
- Instructions on when the drain can be removed and by whom.
- Who to contact if the patient becomes unwell.

If the operator is not part of the medical team looking after the patient, then they should handover that the procedure has been completed and if any complications occurs and post procedure care that is required.

Team Debrief:

A debrief should take place between the operator and assistant after the handover has taken place. This should happen away from the patient's bedside in a private part of the ward.

The debrief which should include (See appendix C Paracentesis checklist):

- Things that went well
- Any problems with equipment or other issues
- Areas for improvement
- A named person for escalating issues

Following this, an entry into the ward's paracentesis procedures log book should be made, it should include the date and time, patient name, operator and assistant.

been drained, or the drainage has slowed to a						
minimum.						
Standard duration of drain is 6 hours before removal.	To minimise the risk of infection					
In malignant ascites the drain can be left in for up to						
48 hours but only if the rate of drainage has not						
significantly slowed.						
The patient should be asked to lie on the opposite	Lying on the opposite side minimises the risk of					
side to the drainage site for removal	leakage from the site					
Apply a sterile gauze and adhesive dressing to the area.	To maintain asepsis and protect the wound					
If leakage is heavy, a stoma bag may be required						
(Sometimes patients need a stoma pack over the site						
for several days). Sutures are rarely required.						

STANDARD OPERATING PROCEDURE (SOP)	Issue date: 22/07/2019
Trust Reference Number: C31/2019	Revision date: October 2023
University Hospitals of Leicester NHS	
NHS Trust	Review date: October 2026
Leicester Royal Infirmary (LRI)	Page 14 of 21 Version: 2
Patients often feel 'washed out' and weak during and Excl	ude possible post procedural complications
in the last few hours after the procedure. Usually rest	
and reassurance (and analgesia if there is discomfort) are sufficient.	
If there is greater cause for concern, check blood	
pressure, assess need for medical review, intravenous	
fluids and consider other complications of	
paracentesis if appropriate.	
Discharge:	
For day case patients, once the drain has been removed and	
the patient should have a lying and standing BP and a full se	
If these are normal, then they should be encouraged to walk	c around to ensure they are steady on their feet
and there is no excessive leakage of fluid.	that the precedure has taken place and the
A discharge letter should be written on ICE that documents amount of ascitic fluid removed.	that the procedure has taken place and the
A decision should be taken by the operator whether the pat	ient should have their
diuretics adjusted depending on the patient's renal function	
tolerance. This should be documented in the discharge lette	-
for follow up and blood monitoring.	
Governance and Audit:	
A safety incident is a breach in the SOP in which the patient	potentially could or did come to harm. All
incidents will be reported on Datix.	
All incidents reported on Datix concerning this procedure wi	II be shared and discussed at staff meetings in all
the areas where this procedure takes place.	
Adherence to the SOP will be initially be audited on an ann	
Each ward's cases will be identified by consulting the ward'	_
of paracentesis procedures. The results will be presented to	o the
monthly Digestive Disease Centre (DDC) meeting.	
To submit monthly Safe Surgery Audit and WHOBARS assess	ment as per Safe Surgery Quality Assurance &
Accreditation programme.	
Training:	
Any new operator will have to demonstrate knowledge of th	isSOP.
New operators, learning the procedure should be supervised	
be gained by formative DOPs recorded in their training port	
achieved the necessary competency to perform the procedu	re independently then a summative DOPs should be
performed and recorded in their training portfolio.	
New ANP and PA operators should be trained in a similar wa equivalent documentation and stored in their training portfo	

Competency in pre-paracentesis ultrasound should be developed and documented in the same way.

What is an abdominal tap/ drain?

An abdominal tap (also know as paracentesis) or drain, is a procedure in which a small tube is inserted into your tummy (abdominal wall) to remove fluid (ascites) from within your tummy.

Why do I need to have it done?

There are 2 reasons for having this procedure:

- To relieve pressure from within your tummy from a build up of fluid (abdominal drain).
- To remove a small amount of this fluid to send to the laboratory to be tested (abdominal tap). You can expect to have the results of this test within a week.

Where will the procedure take place?

- If you are currently staying in hospital, it can take place on the ward that you are on.
- If you are out of hospital and under the care of a cancer team (Oncology), you will go to Osborne Day Care, on the 2nd floor of the Osborne Building at Leicester Royal Infirmary.
- If you are under the care of the liver team (Hepatology), you will go to either ward 43 or 42 at Leicester Royal Infirmary.
- Please let us know if you are on blood thinning medication (anticoagulant) e.g. like warfarin or antiplatelet medication like clopidogrel, at the time when your appointment is being made.

Health information and support is available at www.nhs.uk or call 111 for non-emergency medical advice

University Hospitals of Leicester NHS Trust

What happens when I come to the hospital?

- We will look at your blood test results. These might need to be repeated if necessary.
- Please bring along a list of your medications for us to look at.
- Before the procedure begins you will be asked to use the toilet to empty your bladder.
- A nurse will help you onto the bed and make sure you are in a comfortable position.
- You may be given an injection to numb the skin (local anaesthetic).
- You may have an ultrasound scan during the procedure depending on the cause of the fluid.
- During the procedure, a small tube will be inserted into your tummy via a small cut in the skin. The fluid will drain through this tube into a drainage bag.
- If the fluid build up is due to liver scarring (cirrhosis), you may need to have a drip put in your arm to give you some fluid (human albumin solution 20%), while the extra fluid is draining from your tummy. Human albumin solution is a blood product and has been shown to help the kidneys after a tap.
- When all the fluid has drained (this could be over several hours), the tube is removed and a
 dressing is put over the place where the tube went in.
- You may experience slight discomfort during the procedure, but it should not be painful.
- Painkillers can be given if you experience any discomfort. Tell the nursing staff if this happens.
- If you have any queries please ask your nurse.

What are the benefits of this procedure?

- Having the fluid drained from your tummy will help relieve tummy pain.
- The results of the laboratory test of the fluid sample may help determine why the fluid is there.

What are the risks?

2

- It is a safe procedure with a very small chance of significant side effects (less than 1 in 100 people).
- There is a slight chance that during the procedure a hole is made in the gut. This may cause bleeding or infection. In patients that have cancer as the cause of the fluid, it is common for the fluid that comes out to be blood stained (pinky). This does not necessarily mean there has been a problem caused by the procedure.
- If a large quantity of fluid is removed, there is a slight risk of it making you feel dizzy and affecting the kidney function. Fluid may be given to you through a drip to avoid these problems. Your blood pressure, pulse and temperature will be monitored regularly during the procedure.
- There is a slight chance that the site where the tube is inserted may become infected.

Aftercare

- Some leakage of fluid from the drain site for a few hours after the procedure is common and nothing to worry about. Your nurse will check this before you go home.
- You should remove the dressing from the drain site after 24 hours.
- You should then check the site for redness and other signs of infection. If you are worried that you may have an infection or have other concerns, please contact us using the details below.
- It is certainly possible that the fluid will start to build up again over the following days to weeks. Please contact us if this happens using the details below.

Contact details

If you are feeling unwell immediately after being discharged from hospital:

Liver Unit (Hepatology) patients:

Ward 43, Leicester Royal Infirmary - Tel: 0116 258 6239 or 6279

Osborne Unit (Oncology) patients:

Osborne Day Care - Tel: 0116 258 5263 (Monday to Friday, 9am to 5pm) Outside hours - Oncology Wards, Tel: 0116 258 6339 or 0116 258 6309.

If your tummy is becoming more swollen and painful again and needs a further drain:

There may be a delay of 3 to 4 days before this can be arranged for you to come in.

Liver Unit (Hepatology) patients:

Hepatology Secretary - 0116 258 6480 (Monday to Friday, 9am to 4pm)

Osborne Unit (Oncology) patients:
 Osborne Day Care - Tel: 0116 258 5263 (Monday to Friday, 9am to 5pm)
